

Digital Signal Processing Lab

Demo 54 - Exercise 2 (AM effect with live spectrum)

Saad Zubairi
shz2020

October 29, 2025

Solution

To implement the AM effect, we reused the same real-time microphone acquisition and plotting framework from Question 1, replacing the high-pass filter with a cosine-based amplitude modulator.

This setup multiplies the incoming audio samples by a high-frequency carrier signal, shifting the spectrum to higher frequencies while maintaining real-time playback and visualization.

Overview of Modifications

- **Carrier Initialization:** A 1 kHz cosine carrier was chosen to clearly illustrate frequency translation in the spectrum. The carrier parameters and phase increment were initialized as follows

```
1 f_carrier = 1000.0      # Hz
2 phase = 0.0
3 phase_inc = 2.0 * np.pi * f_carrier / RATE
4
```

- **Amplitude Modulation Process:** For each input block from the microphone, the signal was multiplied by the carrier, producing an amplitude-modulated output signal. The per-block processing loop is identical to the high-pass example except for the multiplication step

```
1 carrier = np.cos(phase + phase_inc * np.arange(BLOCKLEN))
2 y_block = x_block * carrier
3 phase = (phase + phase_inc * BLOCKLEN) % (2.0 * np.pi)
4 y_play = np.clip(y_block, -32768, 32767).astype('int16')
5 stream.write(y_play.tobytes(), BLOCKLEN)
6
```

- **Matplotlib visualization:** The Matplotlib animation setup remains identical to Question 1:
 - Input Signal (time domain)
 - Spectrum of Input (with frequency response 100)
 - Output Signal
 - Spectrum of Output

Addendum: Full implementation

```
